Perform the following all the tasks, and upload on your Github Repository.

Note: Do not push venv folder in the github.

Install Django – Verify Python is installed, then install Django using `pip install django` and confirm the version with `django-admin --version`.

Create a Django project – Run `django-admin startproject myproject` and explore the generated folder structure.

Identify core files – Write a short note explaining the purpose of `manage.py`, `settings.py`, and `urls.py`.

Run the development server – Start the server with `python manage.py runserver` and confirm the default welcome page loads at `http://127.0.0.1:8000/`.

Create a Django app – Run `python manage.py startapp myapp` and list the files it generates.

Register the app – Add `myapp` to the `INSTALLED_APPS` list in `settings.py`.

Create a templates folder – Make a project-level `templates/` folder in the same directory as `manage.py`.

Configure the templates directory – Update the `DIRS` option in the `TEMPLATES` setting to `[BASE_DIR / 'templates']`.

Create your first template – Create `templates/home.html` with basic HTML including a heading and paragraph.

Write a view function – In `myapp/views.py`, create a `home(request)` function that uses `render()` to return `home.html`.

Connect the view to a URL – Import the `home` view in `urls.py` and add `path('', home, name='home')`.

Test the homepage – Run the server and verify `home.html` displays correctly in the browser.

Pass a single variable to a template – Modify the view to send a `context` dictionary with a `name` key, and display it using `{{ name }}`.

Pass multiple variables – Extend the context dictionary to include `name`, `course`, and `semester`, and display all three in the template.

Use an `if` template tag – Add `{% if name %} ... {% endif %}` logic in `home.html` to conditionally display the welcome message.

Use a `for` loop template tag – Send a list of students from the view and use `{% for student in students %}` to display each one.

Create a base template – Build `base.html` containing a header, footer, and a `{% block content %}{% endblock %}` section.

Extend the base template – Modify `home.html` to use `{% extends 'base.html' %}` and fill in the `content` block.

Diagram the request-response flow – Draw/write out the flow: Browser Request → URL → View → Template → HTML Response → Browser.

Summarize MVT architecture – In your own words, explain the roles of Model, View, and Template, and how they work together in Django.
